

Designing subsoil drains

A topographic map with green contour lines. On the left side, a vertical strip shows a different map style with yellow and red lines. A white circle with a crosshair is located on this strip. Two white arrows originate from this circle: one points horizontally to the right, and the other points diagonally down and to the right.

Discharge area: Subsoil drains

- Decide where to discharge the water
- Design UP from discharge point (minimum 1:70)
- Have uniform fall on all pipes

Discharge area: Subsoil drains

- 
- A topographic map showing contour lines. A white circle with a crosshair marks a discharge point on the left edge. Two white arrows originate from this point: one points horizontally to the right, and the other points diagonally down and to the right.
- Open drain
 - Creek
 - Be aware what will happen during flooding
 - Discharge must be above level
 - Design the drain FROM the discharge point upward
 - Uniform fall on all pipes

Subsoil drain pattern:

- 
- Favoured design
 - 30-45° angle
 - Small laterals into larger main
 - Flexible corrugated tile
 - Joints are offset from each other

Determining pipe sizing

- 
- A topographic map with green contour lines is shown on the left side of the slide. A white line with arrows indicates a pipe layout. One arrow points horizontally to the right, while another points diagonally down and to the right. A small circle marks the starting point of the pipe layout on the map.
- Manufacturers supply max flow performance
 - As pipe length increases, friction loss increases
 - Main runs with the slope
 - Laterals run across slope

A fall of .5ft in 49.5 ft is 1:99

- 
- Efficient and simple
 - Laterals same distance apart
 - Uniform drainage for the whole area

Calculating pipe required

112 Practical Drainage for Golf, Sportsturf, and Horticulture

Figure 8.3. An area 147.6 ft $\times$ 295.3 ft (45 m $\times$ 90 m) with a central collector drain with laterals spaced 6.6 ft (2 m) apart at 45° to the collector pipe.

How to size pipe

- 
- A topographic map of a field with contour lines. A drainage line is shown on the left side, with a pipe layout indicated by a series of dots. A white circle with a crosshair is located on the drainage line, with an arrow pointing to the right and another arrow pointing down towards the pipe layout.
- Assume area of 1ac (43,560ft sq)
 - Uniform slope of 1:70, down 295 ft. no cross fall
 - Subsoil drains spaced at 6.6ft, topsoil at 12" HC
2"/hr
 - Rainfall event of 2"/hr

Example of racetrack drainage

Figure 8.8. Subsoil drains installed on the inside 33 ft (10 m) of a race-course.

Sizing drains

- High traffic area with subtle drain cover
- Off back of green
- Realistic sizing
- No additional labor for trimming/maintenance

Installing subsoil drains

Migration
Filter material
Installation techniques

Choosing the right filter material

- Filter material should be made on the basis of type or sand that will surround it
- If the drain is in a fine soil, filter should be a coarse river sand- NOT GRAVEL!

Migration of particles

- 
- 
- Significant amount of fines enter the surrounding soil
 - THIS moves fines into the pipe
 - Quickly collapses the drain, often during first few waterings

Particle migration into coarser gravels

Common mistakes:

- Surround pipe with coarse gravel or crush
- Pea gravel $\frac{1}{4}$ - $\frac{3}{8}$ " often specified
- Overall, these gravels are too large!!

126 Practical Drainage for Golf, Sportsturf, and Horticulture

Figure 9.1. A slotted pipe surrounded with a coarse gravel, illustrating how the surrounding soil has migrated into the voids and reduced the hydraulic conductivity of the filter material to that of the surrounding soil.

Filter material entering pipe

- We are too worried about filter material entering the drain pipe
- If gravel is used, smaller particles will migrate into the large pores

Figure 9.2. A piece of 4-in. (100-mm) slotted drainage pipe surrounded by a coarse washed sand, being shaken on a soil shaker. The trial was carried out with an oven dry sand, and also with the same sand slightly moist.

When to use gravel filter material

A topographic map is shown on the left side of the slide. A white circle with a crosshair is placed on a contour line. Two white arrows originate from this circle: one points horizontally to the right, and the other points diagonally down and to the right.

Only in USGA
spec greens

D15 of the
gravel must not
exceed the D85
of the sand zone

This is the
“Bridging Factor”

Clean filter material

- 
- Make sure no fines in the filter material
 - Use HC of the filter material $>100''/\text{hr}$ (sand without fines)
 - Misconception: Sand will not enter drain pipe except from above. Surface area of slots is less than 1% of pipe surface area.

Bridging factor

- If gravel is too coarse, bridging factor will be too high
- Using finer filter material prevents migration of particles from surrounding soil.

Diameter rating

- 
- When installing subsoil drains, in any situation other than USGA sand, use clean washed sand. NOT pea gravel, or any gravel with a D15 less than 1mm.
 - D15 means 15% of the filler is larger than the specified size, 85% spec.

Installing subsoil drains

- Cut into the area below the soil to be drained
- Make sure sides are vertical
- Avoid subsoil contamination
- Provide uniform slope

Figure 9.5. Subsoil drain cut into the base below the topsoil, with 2 in. (50 mm) of sand surrounding the pipe on all sides.

Installing subsoil drains

1. Clean vertical trenches
2. 2" of sand at bottom of trench
3. Even slope
4. Correct high/low points
5. Lay slits on BOTTOM of trench

*water enters pipe from the bottom

134 Practical Drainage for Golf, Sportsturf, and Horticulture

Figure 9.3. A simple method of determining if the bottom of the trench is at the correct gradient.

Installing subsoil drains

5. Cover the pipe with filter sand 2" surrounding

6. Firm down/light rolling

7. Use commercial joints

Figure 9.4. Water enters drainage pipes from the bottom via the surrounding filter material.

Geofabrics: Never wrap pipes

Fabric on drains are unnecessary

If correct sand has been used, fines will effectively pass through the drainage system

Geo textile drastically reduces drainage rates

Types of pipes

Flexible slotted (agricultural)

- 2-8" diameter
- Commonly used is 4" outer diameter
- Slot size vary
- These pipes self-clean, depositing fines through the ridges
- This process will not block pipes

Types of drain pipes

PVC solid drain pipe – Improved flow for collectors

Multi flow – slit drainage

Atlantis draincell

<http://www.atlantis-corp.com.au/video>

Common drainage mistakes

- 
- Incorrect backfill material
 - Incorrect pipe connectors
 - Misunderstanding of surface and subsurface drainage

Common Drainage mistakes

- 
- Assumption that more water moves laterally
 - Improper fall calculation
 - Insufficient fill below pipe
 - *water fills the pipe from below.....

Drainage installation mistakes

- “makeshift” connectors
- Improper joints
- Crushed tile
- All restrict flow

Common drainage mistakes

- Incorrect filter material promoting migration
- Fines of surrounding soil migrate into large pores
- Drainage lifetime dramatically reduced

Smart installation

- Small basin marks lateral connection
- Adds surface drainage outlet
- Easily accessed for flush, or sub-air vacuum

Sizing drains

- High traffic area with subtle drain cover
- Off back of green
- Realistic sizing
- No additional labor for trimming/maintenance

Slit Drainage

<http://tdsdrainage.com/articles.html>

What is Slit drainage?

- The remedial method of quickly removing surface water
- Often done on fairways, or sports fields constructed with heavier soil
- A means of “fixing” poorly drained sportfields

Slit drainage

- Series of narrow vertical trenches backfilled with sand
- Some have pipes in bottom
- Connected to larger connectors to stormwater outlets
- Many work for awhile, but then fail
- A method improving surface drainage

Spacing

The closer
spaced, the
better they work

Average spacing
is 6.6ft

Ensure pipes at
bottom of trench
can accept the
surface water

Design and planning steps

Typical slit and collector

Lateral direction

- Typical installation
- Laterals across slope
- Larger collector drain

Figure 11.2. A typical design with laterals running across the slope feeding into a larger collector drain running down the slope.

Slit Drainage: Greens

Should ALWAYS include a pipe in the trench

Use Geo fabric in the trenches below the pipes

Sand in slits fits USGA specification

Re sodded ONLY by washed turf

Trenching the surface

All trench material removed

Edges must remain sharp and clean

Mound the sand in trench

Figure 11.4. Sand slightly overfilling the trench, then compaction and levelling.

Perched water table in trenches? unnecessary

- Grassing trench lines
- Gravel layer install
- Prevents drying
- Perches the table

Figure 11.3. A trench with gravel in the bottom that perches a water table and prevents the top from drying out excessively in the summer time.

Summary of Slit drainage

- 
- None further than 6.6ft
 - Pipes in ALL trenches
 - Design for excessive rainfall event
 - Trench ACROSS slope
 - Use only USGA sand
 - Geofabric only at bottom of trench
 - Re-sod trench with washed only

Summary continued

Slit drainage is
SURFACE drainage

Topdressing must
continue with sand
used in the trenches

After time the sod must
be stripped off the slits.
(contamination)

Slit drainage on Fairways

Drainage

REVIEW

Name 2 examples of moisture-related diseases that can be avoided with good drainage.

- Pythium root rot
- Pythium blight
- Rhizoctonia brown patch

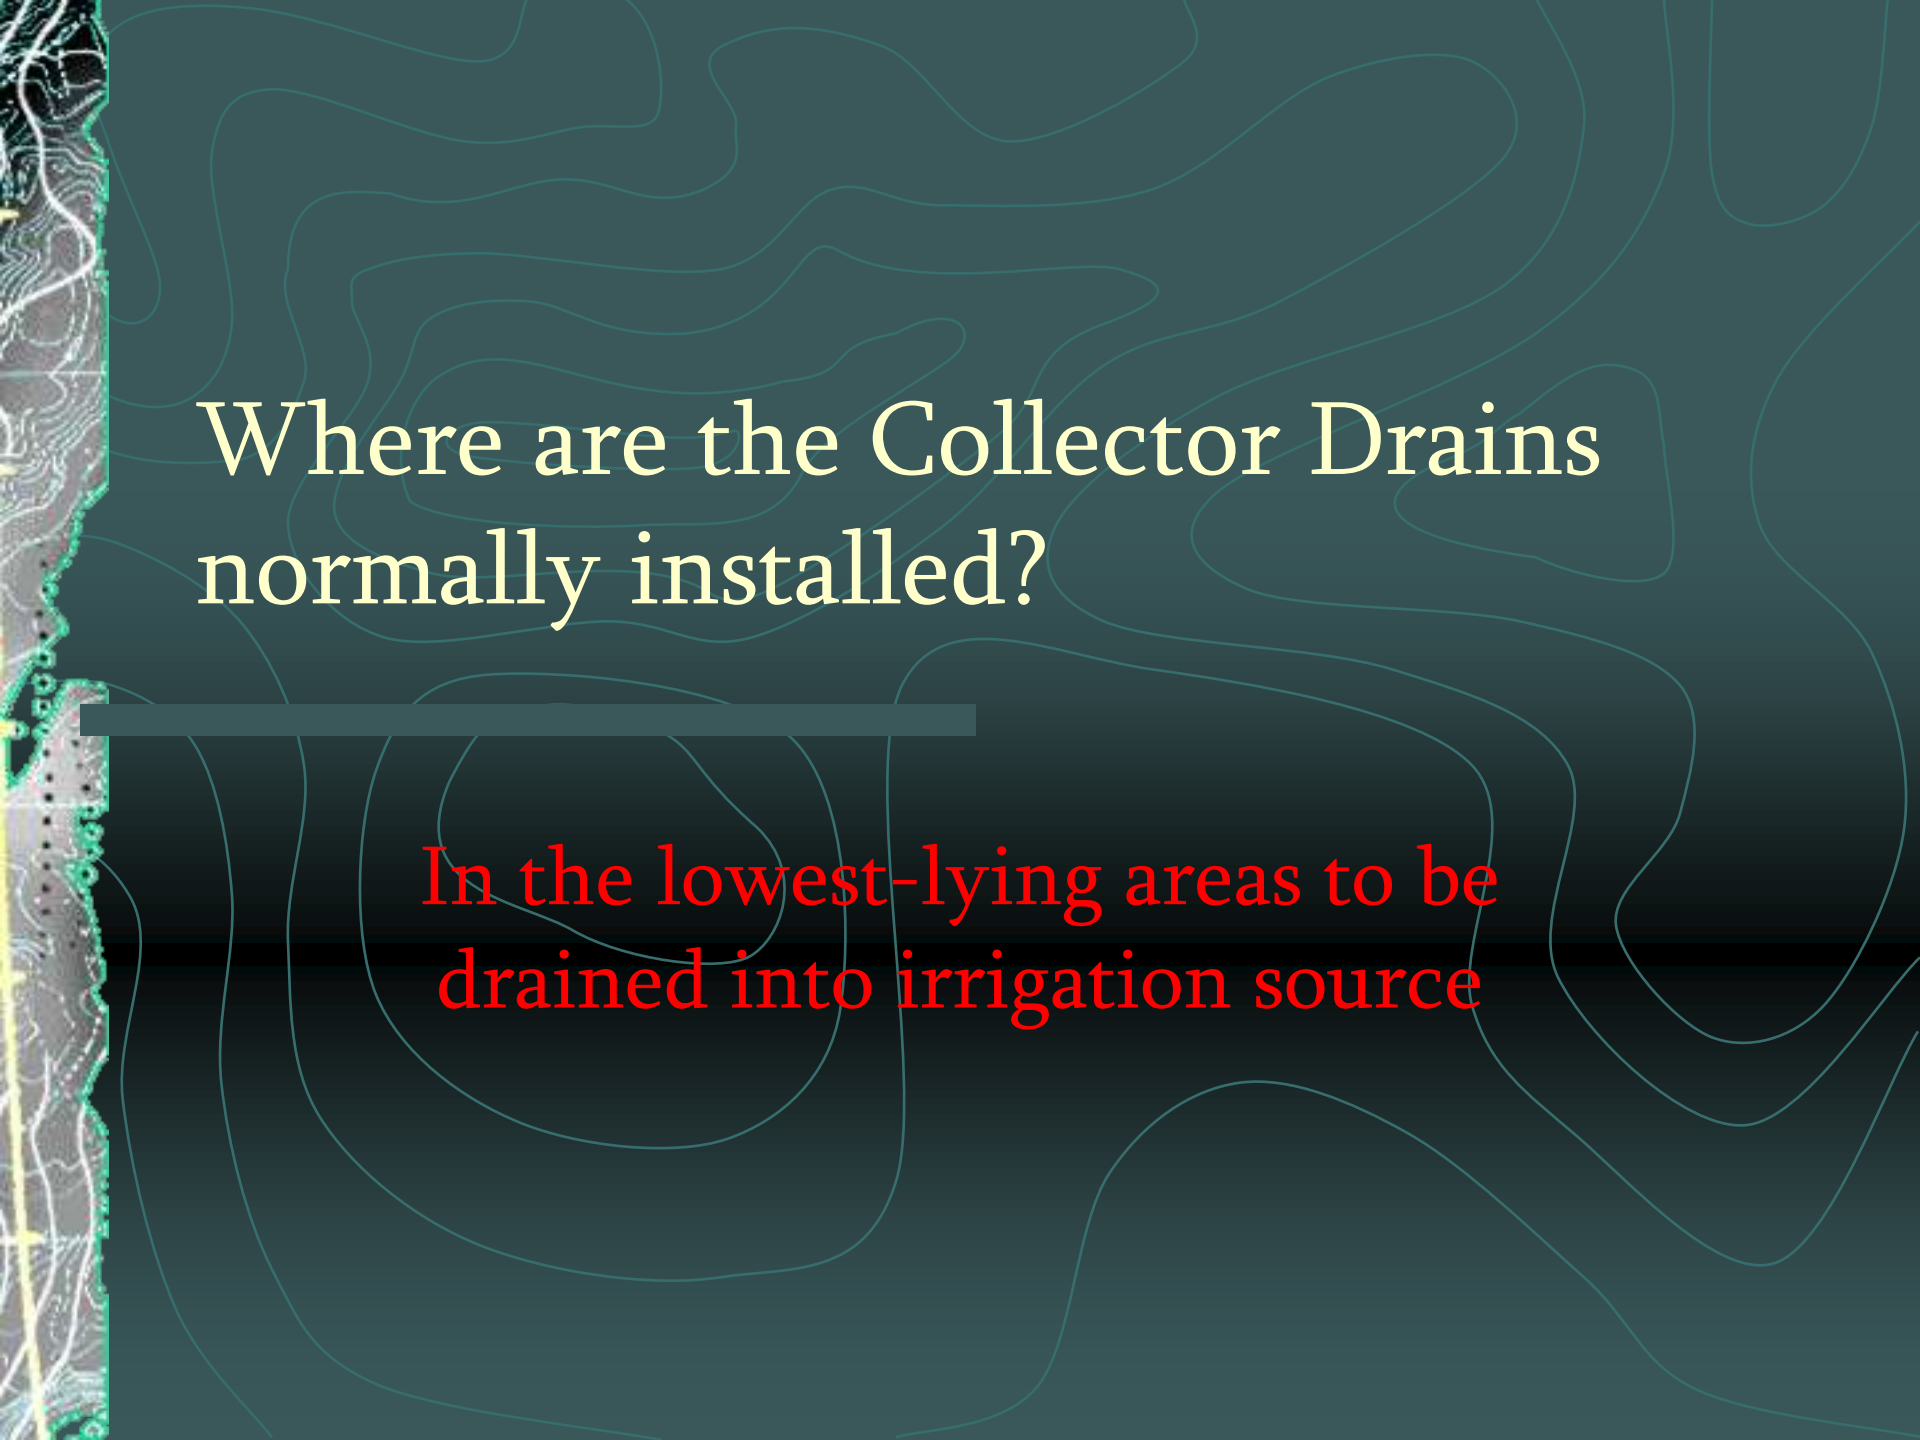

Name 3 advantages to good drainage:

- 
- less compaction to well-drained soil
 - Better water absorption after a rainfall
 - Improvement of subsoil moisture conditions

A topographic map of a golf course is shown on the left side of the slide. It features contour lines indicating elevation, with a yellow line likely representing a fairway or path. The map is partially obscured by the text and a dark horizontal bar.

What is the name of the longest
and deepest drains on a golf course?

Main Collector Drains

A topographic map of a drainage basin is shown on the left side of the slide. It features contour lines indicating elevation, a network of stream channels, and a yellow line representing a proposed or existing drainage system. The map is oriented vertically, with the top of the basin at the top of the image.

Where are the Collector Drains normally installed?

In the lowest-lying areas to be drained into irrigation source

How can Slit Drainage save an older green from being totally rebuilt?

allows excess water to escape before it can freeze and cause damage to the surface on older push-up style greens.

What is the limitation of slit drainage?

Trenches must remain open

- Routinely opened, or top dressed

What options are possible for this low lying “mogul” drainage repair?

- French drain
- Lateral to collector
- Re-grade and sod

WHAT IS THE SLOPE & RUN RULE OF THUMB WHEN DESIGNING DRAINAGE?

3% SLOPE, MINIMUM 1%, MAX RUN IS 1:70

A vertical strip on the left side of the slide shows a topographic map of a fairway drainage system. It features contour lines, a network of white lines representing drains, and a yellow line indicating a specific path or boundary.

EXPLAIN THE RELATIONSHIP OF A LATERAL, CATCH BASIN, AND COLLECTOR IN FAIRWAY DRAINAGE.

**LATERAL IS SUBSURFACE DRAINAGE SYSTEM
TO MEET THE COLLECTOR UNDERGROUND, A
CATCH BASIN INTERCEPTS SURFACE WATER
AND IS CONNECTED TO MAIN COLLECTOR**

HOW DO CONTOUR MAPS ILLUSTRATE THE BEST PLACE FOR AN IRRIGATION POND?

CONTOUR MAPS ILLUSTRATE THE LOWEST POINT ON THE GOLF COURSE. IDEALLY, NATURAL DRAINAGE WILL OCCUR INTO THIS AREA.

**SLIT DRAINS ARE OFTEN USED ON GREENS
AND FAIRWAYS. DO THEY FACILITATE
SURFACE OR SUBSURFACE DRAINAGE?**

**SLIT DRAINAGE ARE SURFACE WATER
DRAINAGE**

**FOLLOWING A SLIT DRAINAGE
PROJECT, WE SOD THE TRENCHES.....TRUE
OR FALSE?**

False

<http://www.hydraway.net/video.php>

HYDRAWAY DRAINAGE SYSTEM

A vertical strip on the left side of the slide shows a topographic map of a river valley. The map features contour lines, a river channel, and some infrastructure like roads and bridges. The colors are muted, with greens for vegetation and browns for the river and surrounding land.

Hydraway states their product is a subsurface drainage system. This statement is only minutely correct. Explain

-
- **This is primarily a surface drainage system.**
 - **Lateral movement of water in soil is so minute in comparison.**

A vertical strip on the left side of the slide shows a topographic map with contour lines and a yellow line representing a drainage path or boundary.

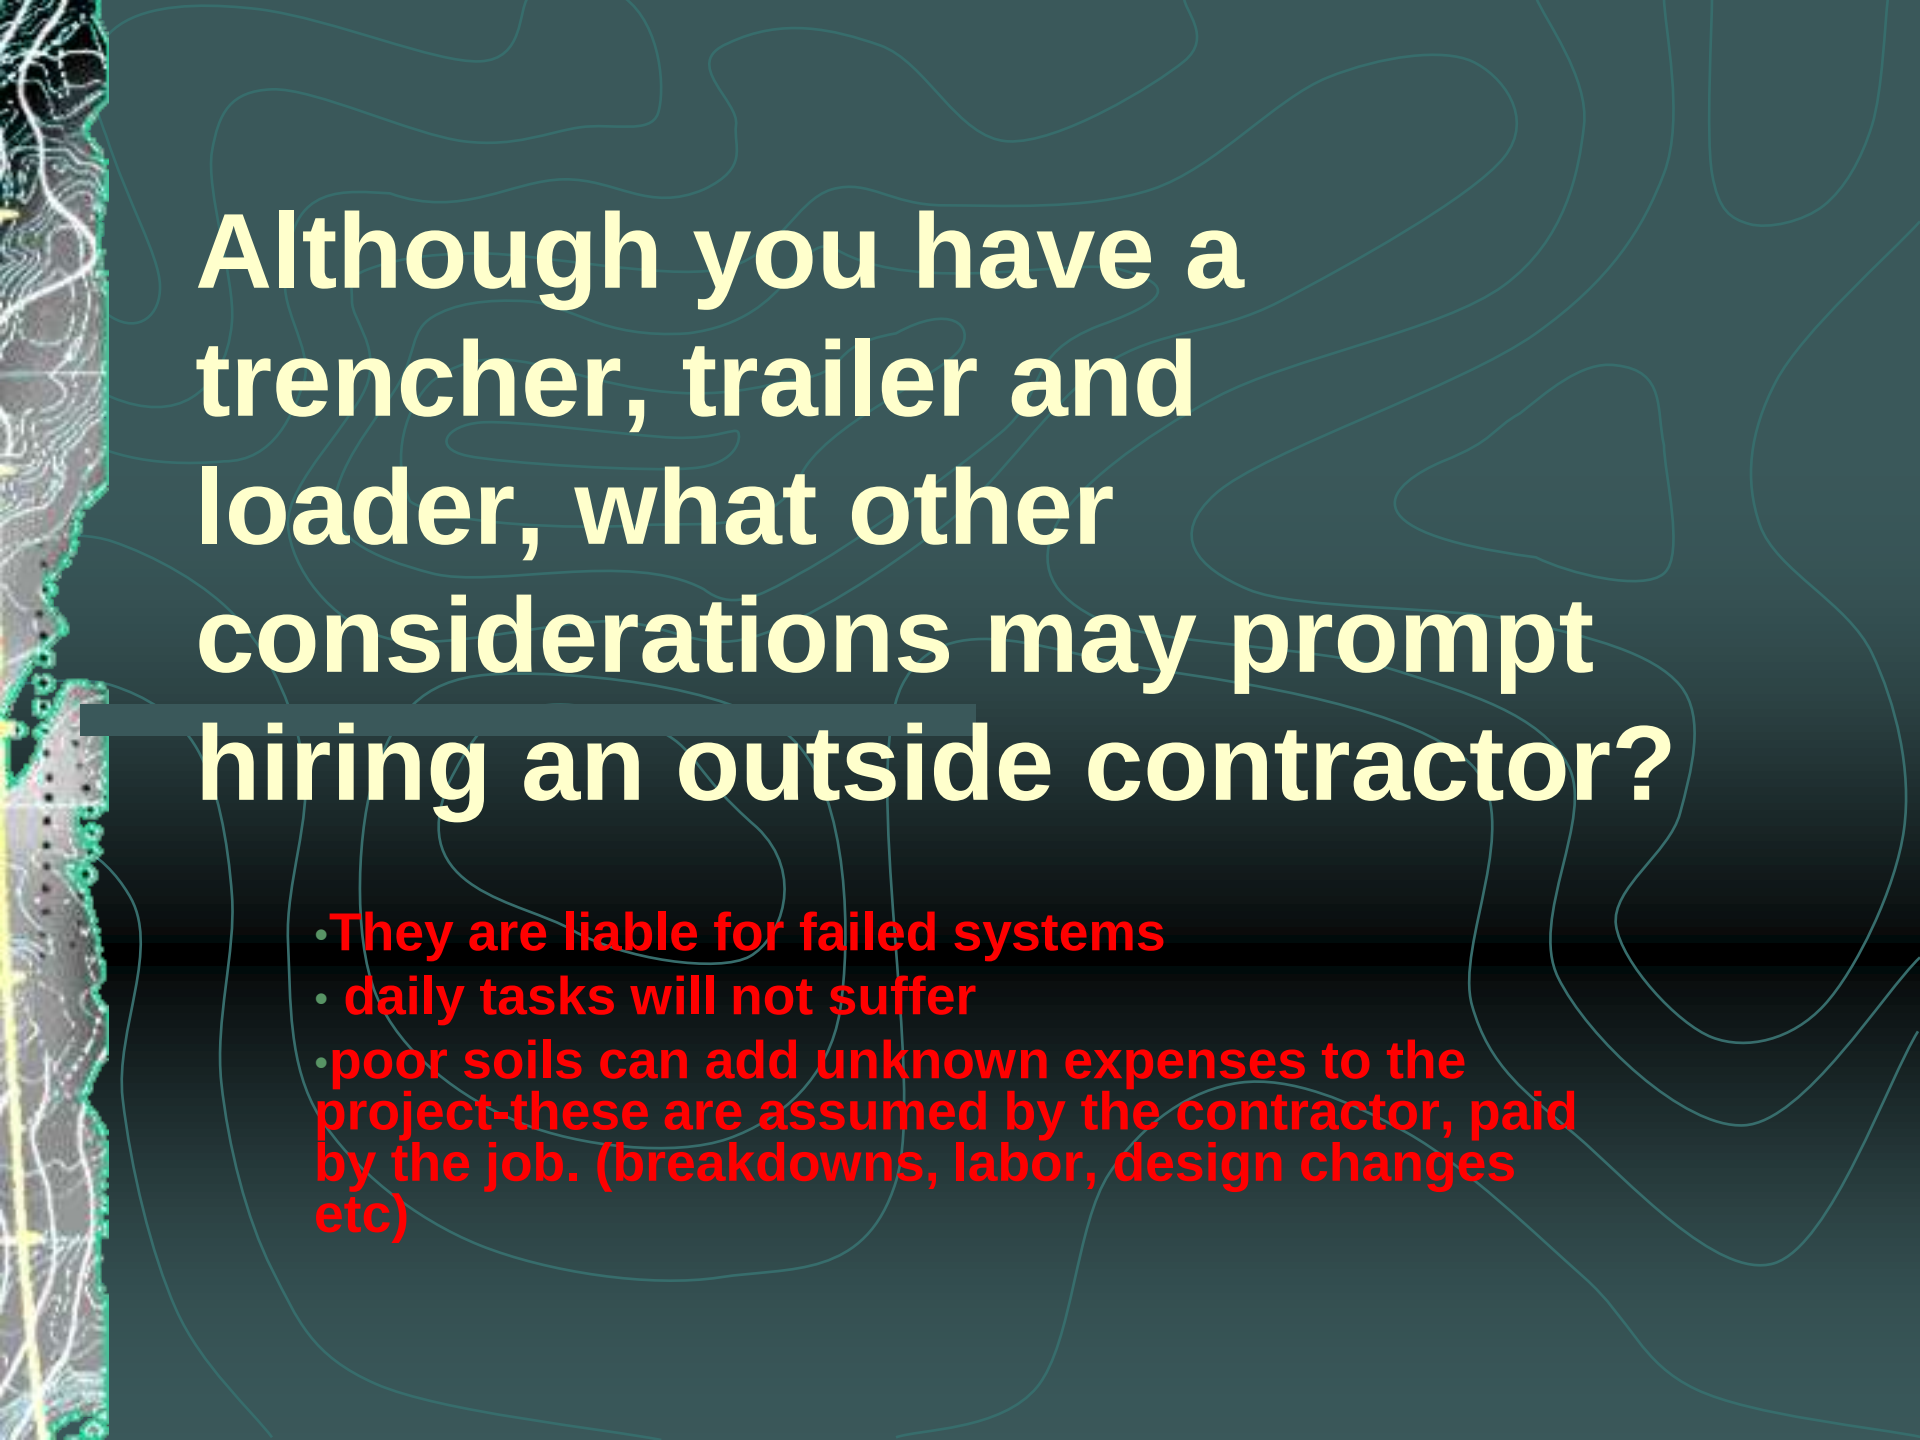

Hydraway states their backfill is coarse sand, providing an “additional filter” to remove clay fines in the soil. Although it does not *remove* fine particles, the design may minimize lateral movement of silt and clay. How?

The impermeable PVC one-sided tile may physically reduce lateral movement of fines from soil to the coarse sand.

A vertical strip on the left side of the slide shows a topographic map with contour lines and a drainage network. The map is oriented vertically, with the drainage network flowing downwards. The background of the slide is a dark teal color with light blue contour lines.

Would the Hydraway system work without the tile? What advantages does the tile really offer?

- Yes, backfilling with coarse sand will facilitate equivalent surface drainage properties.
- The strength of the PVC tile will add to trench longevity by preventing collapse by repeated traffic

Although you have a trencher, trailer and loader, what other considerations may prompt hiring an outside contractor?

- They are liable for failed systems
- daily tasks will not suffer
- poor soils can add unknown expenses to the project-these are assumed by the contractor, paid by the job. (breakdowns, labor, design changes etc)

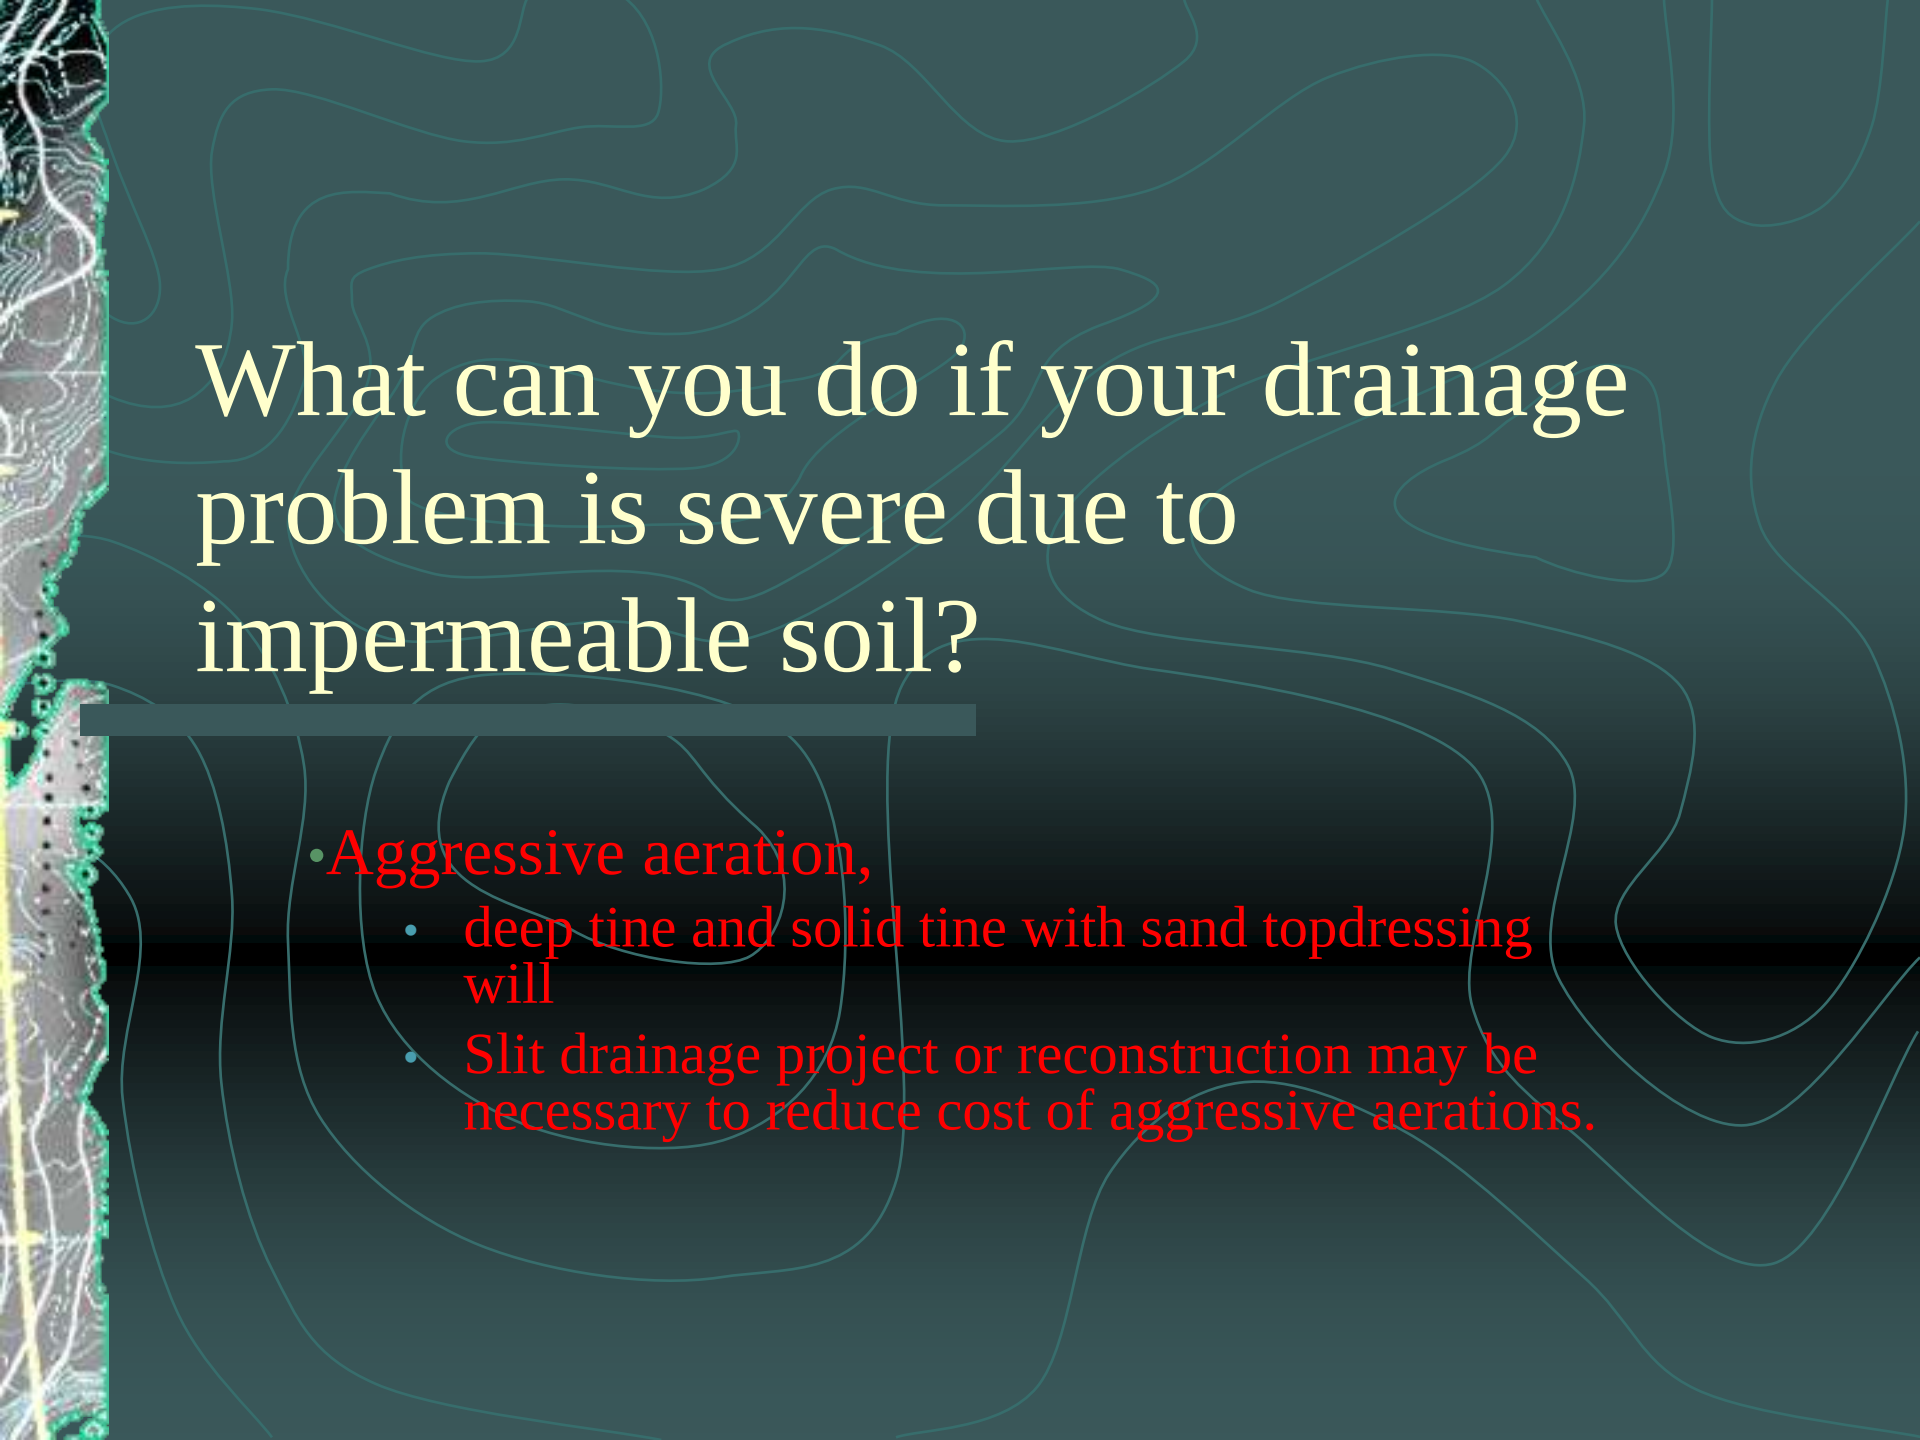

Although the advantages of using slit drainage as effective surface drainage outweigh the disadvantages, what additional concerns may you have if performing this project on a putting green?

- Trench lines should not be sodded unless with washed sod so not to contaminate coarse sand in the trench.
- Slit drainage is not a permanent solution, and may need to be done every couple of years.

How can trees contribute to poor drainage?

by blocking sunlight and air circulation, which reduces both evaporation and transpiration of moisture from the turf canopy.

A topographic map of a golf course is visible on the left side of the slide, showing various green areas, fairways, and water features. The map is oriented vertically, with the top of the slide showing the upper part of the course and the bottom showing the lower part. The map is overlaid with a dark blue background that features a pattern of light blue, wavy, concentric lines, resembling a stylized topographic map or a decorative background.

What can you do if your drainage problem is severe due to impermeable soil?

- Aggressive aeration,
 - deep tine and solid tine with sand topdressing will
 - Slit drainage project or reconstruction may be necessary to reduce cost of aggressive aerations.

Indicate probable cause, effect, and solution to this putting green issue.

1. The water cannot run off due to depressions or in this case, a high collar.
2. With no subsurface drainage, the water stays on the surface
3. Recommend collar renovation to facilitate surface runoff, core aeration to improve subsurface drainage.

This tee has negative drainage, and illustrates the tee access is bare. Indicate three solutions to improve the tee.

- Install cut-off drain at base of retaining wall
- Re-grade the tee to 1-3% slope
- Increase size of tee access to rotate traffic

What could be the cause, and how would you remedy to this fairway drain?

- the drain line was not graded correctly, and sits too low.
- Surface water enters the trench, but does not flow, causing localized anaerobic conditions commonly found where algae is present.
- The lateral needs to be dug up, and graded to recommended 3% slope.

What kind of drain would you employ here? Why?

- A) French drain: 4" perforated drain tile, covered coarse sand
- B) Adequate surface grate
- C) Cut sod and re-grade 1-3% slope facilitate surface run-off to grate or off fairway
